

30July2026-I16W2

The two pie charts illustrates proportion of production of electricity from various sources in Scotland from two decades ago and previous year.

Overall, Coal remained the largest source of energy, although it shares declined significantly. In contrast, significant growth is seen in production of Nuclear energy & other renewables source, while Gas, Hydro pumped storage, Oil and Hydro natural flow shown almost no deviation.

Two decade ago, coal accounted for the highest proportion of electricity production at 41.4%. Gas & Nuclear, being the second & third largest, shown nearly a fifth of whole. While, Hydro natural flow, hydro pumped storage and other renewables marginally contributed at 8.7%, 3.1% and 2.8% respectively,. The smallest impact is made by Oil at 2.1%.

In previous year, Coal still made the largest impact but fell significantly to a little less than one-third. Similarly, Gas and Hydro natural flow shown a slight negative deviation, from 8.7% to 7.9% and 22.3% to 21.7% respectively. While, Nuclear, still being second largest, went from being a fifth to a quarter proportion. In addition, Oil, a non-renewable source, depicted a positive deviation at a whole four percent. Also, Other renewable sources also shown increasing proportion i.e from 2.8% to 5.1%. In contrast to oil share of 20 years ago, This time Hydro pumped storage being the least share, at just 2.2%.
